THE SIMULATION OF INTERIOR BALLISTIC PERFORMANCE OF
GUNS BY DIGITAL COMPUTER PROGRAM

ABSTRACT

When non-conventional guns are to be considered or when detailed design information is required, interior ballistic calculations become more difficult and time-consuming. To deal with these problems, the equations which describe the interior ballistic performance of guns and gun-like weapons have been programmed for the high-speed digital computers available at the Ballistic Research Laboratories. The major innovation contained in the equations derived in this report is the provision for use of propellant charges made up of several propellants of different chemical compositions and different granulations. Results obtained by the method described in this report compare favorably with those of other interior ballistic systems. In addition, considerably more detail is obtained in far less time. A comparison with experimental data from well-instrumented gun-firings is also presented to demonstrate the validity of this method of computation.

 ρ_i density of i th solid propellant, lb/in.³

INTRODUCTION

The interior ballistician must frequently predict the interior ballistic performance of guns. In some instances, it is sufficient to calculate muzzle velocity and maximum chamber pressure for a conventional gun from a knowledge of the propellant charge, the projectile weight, and the gun characteristics. This calculation is usually referred to as the classical central problem ^{(1)*} of interior ballistics. When non-conventional guns are considered or when detailed design information is required, it is necessary to know more than these two salient values. For the more demanding problems, complete interior ballistic trajectories may have to be calculated. These trajectories consist of displacement, velocity, and acceleration of the projectile and chamber pressure, all as functions of time.

The literature of interior ballistics contains descriptions of many methods for solving the problem of predicting the performance of guns. ⁽¹⁾ ⁽²⁾ Methods, varying from the purely empirical to the "exact" theoretical, have been devised in tables, graphs, nomograms, slide rules, and simplified equations solved in closed-form. Some of these methods require data from the firing of the gun being considered or from a very similar gun. All of these methods require some simplification of the basic equations of interior ballistics.

To eliminate the restrictions imposed by assumptions made only to facilitate the mathematical solution of the problem, the interior ballistic equations have been programmed for high-speed electronic computers. Both analog and digital computers have been used to calculate detailed interior ballistic trajectories. There are advantages and disadvantages associated with each type of computer. Several years ago, ⁽³⁾ the interior ballistic equations were programmed for the digital computers** available here at the Ballistic Research Laboratories. Since that time, considerable use has been made of this program for studying gun and gun-like systems and for routine calculations.

* Superscripts indicate references listed at the end of this report.

** Although the interior ballistic equations were originally programmed only for the ORDVAC, ⁽⁴⁾ they have been recently reprogrammed in more general form ⁽⁵⁾ for the ORDVAC and the newer BRLESC. ⁽⁴⁾

The computer program described in this report has been designed to solve a set of non-linear, ordinary differential and algebraic equations which simulate the interior ballistic performance of a gun. In this method, the usual set of equations which pertains to the burning of a single propellant has been modified to account for the burning of composite charges, i.e., charges made up of several propellants of different chemical compositions and different granulations.* The computer program may be suitably modified to study non-conventional guns and gun-like systems. A number of these optional programs have been devised and used extensively.**

INTERIOR BALLISTIC THEORY

Interior Ballistic System

The basic components of the interior ballistic system for a conventional gun are shown in Figure 1. A set of equations can be formulated which mathematically describes the distribution of energy originating from the burning

Figure 1. Basic Components of the Interior Ballistic System for a Conventional Gun

* The present program can be operated with as many as five different types of propellant charges for each problem.

** See Section entitled Options to Routine.

propellant and the subsequent motion of the components of the system. In the development which follows, two major assumptions are made to account for the behavior of composite charges:

1. The total chemical energy available is the simple sum of the chemical energies of the individual propellants.

2. The total gas pressure is the simple sum of the "partial pressures" resulting from the burning of the individual propellants.

Energy Equation

Application of the law of conservation of energy leads to the energy equation of interior ballistics. This may be written as:

$$\begin{array}{lcl} \text{Energy Released} & = & \text{Internal Energy} \\ \text{by Burning Propellant} & & \text{of Propellant Gases} + \text{External Work Done} + \text{Secondary} \\ & & \text{on Projectile} \quad \text{Energy Losses} \end{array} \quad (1)$$

or:

$$Q = U + W + \text{Losses} \quad (1a)$$

In Equation (1a) the energy released by the burning propellant (Q) is assumed to be equal to the simple sum of the energies released by the individual propellants as previously stated. Therefore:

$$Q = \sum_{i=1}^n \left[C_{i1} z_{i1} \int_0^{T_{O1}} c_{v1} dT \right] \quad (2)$$

Because of gas expansion and external work performed in a gun, the gas temperature is less than the adiabatic flame temperature (T_{O1}). The internal energy of the gas (U) is then:

$$U = \sum_{i=1}^n \left[C_{i1} z_{i1} \int_0^T c_{v1} dT \right] \quad (3)$$

The external work done on the projectile is given by:

$$W = A \int_0^x p_b dx \quad (4)$$

Substituting Equations (2), (3), and (4) into Equation (1a) gives:

$$\sum_{i=1}^n \left[C_{i1} z_{i1} \int_0^{T_{O1}} c_{v1} dT \right] = \sum_{i=1}^n \left[C_{i1} z_{i1} \int_0^T c_{v1} dT \right] + A \int_0^x p_b dx + \text{Losses}$$

which may be rewritten as:

$$\sum_{i=1}^n \left[C_{i1} z_{i1} \int_T^{T_{O1}} c_{v1} dT \right] = A \int_0^x p_b dx + \text{Losses} \quad (5)$$

As the c_{v1} do not vary greatly over the temperature ranges from T to T_{O1} ,

they can be replaced with mean values (\bar{c}_{v1}). Integration of Equation (5) gives:

$$\sum_{i=1}^n C_{i1} z_{i1} \bar{c}_{v1} (T_{O1} - T) = A \int_0^x p_b dx + \text{Losses} \quad (6)$$

and solving for T :

$$T = \frac{\sum_{i=1}^n C_{i1} z_{i1} \bar{c}_{v1} T_{O1} - A \int_0^x p_b dx - \text{Losses}}{\sum_{i=1}^n C_{i1} z_{i1} \bar{c}_{v1}} \quad (7)$$

Next, the "force" of each propellant is defined by:

$$F_1 = m_1 R T_{O1} \quad (8)$$

and the well-known relations:

$$\bar{c}p_1 - \bar{c}v_1 = m_1 R \quad (9)$$

and:

$$\gamma_1 = \frac{\bar{c}p_1}{\bar{c}v_1} \quad (10)$$

are introduced.

Combination of Equations (9) and (10) gives:

$$\bar{c}_{v_1} (\gamma_1 - 1) = m_1 R \quad (11)$$

Substitution of Equation (11) into Equation (8) gives:

$$T_{o_1} = \frac{F_1}{(\gamma_1 - 1) \bar{c}_{v_1}} \quad (12)$$

Finally, substitution of Equation (12) into Equation (7) gives R  sal's equation in the form:

$$T = \frac{\sum_{i=1}^n \frac{F_i C_i z_i}{\gamma_i - 1} - A \int_0^x p_b dx - \text{Losses}}{\sum_{i=1}^n \frac{F_i C_i z_i}{(\gamma_i - 1) T_{o_i}}} \quad (13)$$

For most problems, it is convenient to assume the igniter completely burned ($z_I = 1$) at zero-time. Equation (13) may be restated as:

$$T = \frac{\left[\sum_{i=1}^n \frac{F_i C_i z_i}{\gamma_i - 1} \right] + \frac{F_I C_I}{\gamma_I - 1} - A \int_0^x p_b dx - \text{Losses}}{\left[\sum_{i=1}^n \frac{F_i C_i z_i}{(\gamma_i - 1) T_{o_i}} \right] + \frac{F_I C_I}{(\gamma_I - 1) T_{o_I}}} \quad (14)$$

The terms $A \int_0^x p_b dx$ and Losses of Equation (14) can now be considered in more detail. The work done on the projectile results in an equivalent gain in kinetic energy of the projectile except for losses. Including these losses under the general category of energy losses:

$$A \int_0^x p_b dx = 1/2 \frac{W_P}{g} v^2 \quad (15)$$

According to Hunt, ⁽²⁾ the energy losses to be considered are:

- (1) kinetic energy of propellant gas and unburned propellant,
- (2) kinetic energy of recoiling parts of gun and carriage,
- (3) heat energy lost to the gun,
- (4) strain energy of the gun,
- (5) energy lost in engraving the rotating band and in overcoming friction

down the bore,

and

- (6) rotational energy of the projectile.

For discussion of each type of secondary energy loss, see Reference (2).

Types (2), (4), and (6) are estimated to be less than one percent for each category and have been neglected here.

The kinetic energy of propellant gas and unburned propellant can be represented by ⁽⁶⁾

$$E_p = \frac{\left(\sum_{i=1}^n c_i \right) v^2}{2g\delta} \quad (16)$$

The energy losses resulting from heat lost to the gun can be estimated by a semi-empirical relationship described by Hunt: ⁽²⁾

$$E_h = \frac{0.38c^{1.5} \left(x_m + \frac{v_o}{A} \right) \left(\frac{\sum_{i=1}^n c_i T_{o_i}}{\sum_{i=1}^n c_i} - T_s \right) v^2}{\left[1 + \frac{0.6c^{2.175}}{\left(\sum_{i=1}^n c_i \right)^{0.8375}} \right] v_m^2} \quad (17)$$

At the present time, the introduction of a more sophisticated treatment of heat loss, with its attendant complexity, does not seem to be warranted. Such a substitution can be made if and when it appears desirable.

The final energy losses to be considered here consist of those resulting from engraving of the rotating band, friction between the moving projectile and the gun tube, and acceleration of air ahead of the projectile. Individual estimates of these are difficult to make, so they have been grouped as resistive pressure in the form:

$$E_{p_r} = A \int_0^x p_r dx \quad (18)$$

The p_r versus x function is discussed in greater detail in the section concerning forces acting on the projectile.

Substitution of Equations (15), (16), (17), and (18) into Equation (14) results in the form of the energy equation used in this computer program:

$$T = \frac{\left[\sum_{i=1}^n \frac{F_i C_i z_i}{\gamma_i - 1} \right] + \frac{F_I C_I}{\gamma_I - 1} - \frac{v^2}{2g} \left(W_p + \sum_{i=1}^n \frac{C_i}{\epsilon} \right) - A \int_0^x p_r dx - E_h}{\left[\sum_{i=1}^n \frac{F_i C_i z_i}{(\gamma_i - 1) T_{o_i}} \right] + \frac{F_I C_I}{(\gamma_I - 1) T_{o_I}}} \quad (19)$$

Equation of State

The pressure acting on the base of the projectile can be calculated from a series of equations, once the temperature of the gas is determined from the energy equation. Generally, the equation of state for an ideal gas takes the form:

$$p_1 V_1 = m_1 RT \quad (20)$$

where V_1 = the volume per unit mass of 1 th propellant gas.

Now, define V_c , the volume behind the projectile which is available for propellant gas, as:

Volume Available for Propellant Gas	=	Initial Empty Chamber Volume	+	Volume Resulting from Projectile Motion
	-	Volume Occupied by Unburned Solid Propellant	-	Volume Occupied by Gas Molecules (covolume) (21)

or:
$$V_c = V_o + Ax - \sum_{i=1}^n \frac{C_i}{\rho_i} (1-z_i) - \sum_{i=1}^n C_i z_i b_i$$
 (22)

By the definitions of Equations (20) and (21),

$$V_i = \frac{V_c}{C_i z_i} \quad (23)$$

Substituting Equations (8) and (23) into Equation (20) and rearranging gives:

$$p_i = \frac{F_i C_i z_i T}{V_c T_{o_i}} \quad (24)$$

If the b_i are assumed to be constants over the temperature range from T to T_{o_i} , and if the total gas pressure is taken as the simple sum of the "partial pressures" resulting from the burning of the individual propellants as previously stated, then:

$$\bar{p} = \sum_{i=1}^n p_i = \frac{T}{V_c} \sum_{i=1}^n \frac{F_i C_i z_i}{T_{o_i}} \quad (25)$$

As before, if it is assumed that the igniter is completely burned ($z_I = 1$) at zero-time, Equation (25) may be restated as:

$$\bar{p} = \frac{T}{V_c} \left[\left(\sum_{i=1}^n \frac{F_i C_i z_i}{T_{o_i}} \right) + \frac{F_I C_I}{T_{o_I}} \right] \quad (26)$$

The space-mean pressure, \bar{p} , given by Equation (26) is used in the calculation of the fraction of propellant burned at any time. This relationship is discussed in the section concerning burning rates. There is, however, a pressure gradient from the breech of the gun to the base of the projectile which must be considered in developing the equations of motion for the projectile. This pressure-gradient problem was first considered by Lagrange and is commonly referred to as the Lagrange Ballistic Problem. Later studies in this area were made by Love and Pidduck, (7) Kent, (8) and others. For this computer program, the improved Pidduck-Kent solution developed by Vinti and Kravitz (6) has been used:

$$p_b = \frac{\bar{p}}{1 + \frac{\sum_{i=1}^n c_i}{w_p \delta}} \quad (27)^*$$

In addition the breech pressure, p_o , is calculated by the method contained in Reference (6). This is the pressure usually measured in experimental interior ballistic studies:

$$p_o = \frac{p_b}{(1-a_o)^{-n'-1}} \quad (28)$$

$$\text{where: } 1/a_o = \frac{2n'+3}{\delta} + \frac{2(n'+1)}{\sum_{i=1}^n c_i/w_p} \quad (28a)$$

* In Reference (6), the determination of δ depends on the ratio of specific heats, γ . For composite charges, an effective value is used for this purpose.

$$\gamma' = \frac{\sum_{i=1}^n c_i \gamma_i}{\sum_{i=1}^n c_i} \quad (27a)$$

$$\text{and } n' = \frac{1}{\gamma' - 1} \quad (28b)$$

Mass-Fraction Burning Rate Equation

Both the energy equation (Equation (19)) and the equation of state (Equation (26)) are algebraic equations whose solutions depend upon the solutions of several non-linear, ordinary differential equations. The mass-fraction burning rate equation expresses the rate of consumption of solid propellant and hence the rate of evolution of propellant gas. This may be written as:

$$\frac{dz_1}{dt} = \frac{1}{V_{g_1}} S_1 r_1 \quad (29)$$

$$\text{where: } r_1 = R_1 (\bar{p}) \quad (30)$$

$$\text{and: } S_1 = f_1 (z_1) \quad (31)$$

For most gun propellants, Equation (30) may be quite satisfactorily stated as:

$$r_1 = \beta_1 (\bar{p})^{\alpha_1} \quad (32)$$

For certain propellants, including those plateau and mesa types used in solid-fuel rockets, Equation (32) will not suffice for gun calculations. In these cases, it is preferable to make use of a tabular listing of r_1 's and corresponding \bar{p} 's (Equation (30)) and to interpolate for the desired r_1 . The r_1 's calculated by either Equation (30) or Equation (32) are closed chamber burning rates. As discussed in later sections of this report, these burning rates may be increased by addition of factors proportional to the velocity and displacement of the projectile in the following manner:

$$r_1' = r_1 + K_v v + K_x x \quad (32a)$$

Similarly, the form function described by Equation (31) may be stated in one of several ways. In many interior ballistic systems, the form function is chosen for convenience of analytical solution. Where routine numerical computations are handled by use of a high-speed digital computer, the geometrical form of the propellant grain may be used to obtain the functional relationship, f_1 , between S_1 and z_1 . For the usual grain shapes encountered, these equations are given in Appendix A. This Appendix also contains the method for handling such equations in the computer routine. To extend these equations to include propellant slivering see Reference (9).

Equations of Projectile Motion

The translational motion of the projectile down the gun tube may be calculated from the forces acting on the projectile. Figure 2 shows the axial forces considered in determining the resultant force.

Figure 2. Axial Forces Acting on Projectile

The propulsive force, F_p , is that resulting from the pressure of the propellant gas on the base of the projectile according to:

$$F_p = p_b A \quad (33)$$

where p_b is obtained from Equation (27).

The frictional force, F_f , is the retarding force developed by resistance between the bearing surfaces of the projectile and the inside of the gun tube. This is usually the resistance between the rotating band and the rifling of the tube and includes the force required to engrave the rotating band. It may be expressed as:

$$F_f = p_r A \quad (34)$$

The determination of p_r is difficult in most cases. Many interior ballistic solutions use an increased projectile mass (approximately 5%) to account for its effect. There are several disadvantages inherent in such a treatment. Although the muzzle velocity may be calculated reasonably well, the detailed trajectory will be altered considerably. It is not possible to simulate the case where a projectile lodges in the bore (see Reference (10) for experimental trajectories for this condition). For this computer program, experimental data of the type given in Reference (11) may be used by inserting a tabulation of the function:

$$p_r = G(x) \quad (34a)$$

The gas retardation force, F_r , is that which results from the pressure of air or gas ahead of the projectile, stated as:

$$F_r = p_g A \quad (35)$$

where p_g is small enough to be neglected except for very high velocity systems, light gas guns, and other special applications. In the discussion of the Energy Equation in the Interior Ballistic Theory Section, p_g was considered a part of p_r .

The resultant force in the axial direction is then:

$$F_a = F_p - F_f - F_r \quad (36)$$

or:

$$F_a = A(p_b - p_g - p_r). \quad (37)$$

The acceleration of the projectile, by Newton's second law of motion, is:

$$a = \frac{A(p_b - p_g - p_r)}{M} \quad (38)$$

or:

$$a = \frac{Ag(p_b - p_g - p_r)}{W_p} \quad (39)$$

Since $a = \frac{dv}{dt}$ and $v = \frac{dx}{dt}$, the velocity of the projectile is given by:

$$v = \int_0^t a \, dt \quad (40)$$

and the displacement of the projectile is given by:

$$x = \int_0^t v \, dt \quad (41)$$

Summary of Interior Ballistic Equations

The equations which are used in the computer program are now summarized for ease of reference.

Energy Equation

$$T = \frac{\left[\sum_{i=1}^n \frac{F_i C_i z_i}{\gamma_i - 1} \right] + \frac{F_I C_I}{\gamma_I - 1} - \frac{v^2}{2g} \left(W_p + \frac{\sum_{i=1}^n C_i}{8} \right) - A \int_0^x p_r \, dx - E_h}{\left[\sum_{i=1}^n \frac{F_i C_i z_i}{(\gamma_i - 1) T_{O_i}} \right] + \frac{F_I C_I}{(\gamma_I - 1) T_{O_I}}} \quad (19)$$

where:

$$E_h = \frac{0.38_c^{1.5} \left(x_m + \frac{v_o}{A} \right) \left(\frac{\sum_{i=1}^n C_i T_{O_i}}{\sum_{i=1}^n C_i} - T_s \right) v^2}{\left[1 + \frac{0.6c^{2.175}}{\left(\sum_{i=1}^n C_i \right)^{0.8375}} \right] v_m^2} \quad (17)$$

Equation of State

$$\bar{p} = \frac{T}{V_c} \left[\left(\sum_{i=1}^n \frac{F_i C_i z_i}{T_{O_i}} \right) + \frac{F_I C_I}{T_{O_I}} \right] \quad (26)$$

$$\text{where: } V_c = V_o + Ax - \sum_{i=1}^n \frac{C_i}{\rho_i} (1-z_i) - \sum_{i=1}^n C_i z_i b_i \quad (22)$$

$$p_b = \frac{\bar{p}}{1 + \frac{\sum_{i=1}^n C_i}{W \delta_p}} \quad (27)$$

$$p_o = \frac{p_b}{(1-a_o)^{-n'} - 1} \quad (28)$$

Mass-Fraction Burning-Rate Equations

$$\frac{dz_i}{dt} = \frac{1}{v_{s_i}} s_i r_i \quad (29)$$

$$r_i = \beta_i (\bar{p})^{\alpha_i} \quad (32)$$

or:

$$r'_i = r_i + K_v v + K_x x \quad (32a)$$

Equations of Projectile Motion

$$a = \frac{Ag (p_b - p_g - p_r)}{W_p} \quad (39)$$

$$v = \int_0^t a \, dt \quad (40)$$

$$x = \int_0^t v \, dt \quad (41)$$

COMPUTATION ROUTINE

The set of non-linear, ordinary differential and algebraic equations, summarized at the end of the previous section, simulates the interior ballistic performance of a gun or gun-like system. A numerical computation routine has been devised for the simultaneous solution of these equations. The generalized flow-diagram for the routine is presented in Appendix B. Using the FORAST language, ⁽⁵⁾ the solution has been programmed for the ORDVAC and BRLESC computers.

Preliminary Routine

To reduce computation time and conserve memory space, a preliminary routine has been introduced. Here all data required for the computation are read into the computer, constant groupings (e.g.,

$$\frac{F_1 C_1}{(\gamma_1 - 1) T_{O_1}}, \quad \frac{F_1 C_1}{(\gamma_1 - 1)}, \quad \frac{C_1}{\rho_1}, \quad \text{etc.,} \quad \text{are calculated and stored}$$

for subsequent use, and data to permanently identify the computer run are printed out. A complete listing of required input data may be found in Appendix C.

Main Routine

The main computational routine is presented in the generalized flow-diagram of Appendix B. To follow the procedure, consider the three sequential phases of the problem:

Phase I - From time of ignition until the projectile starts to move.

Phase II - From time of initial projectile motion until all propellants are consumed.

Phase III - From time of propellant burnout until projectile leaves the gun muzzle.

At the time of ignition (Phase I begins), it is assumed that the igniter is completely burned ($z_I = 1$) and none of the other propellants have started to burn (all $z_i = 0$). The space-mean pressure, consisting only of the igniter pressure, is calculated from:

$$\bar{p} = p_I = \frac{F_I C_I}{V_c} \quad (42)$$

Equation (42) is derived from Equations (19) and (26) by means of the simplifying ignition assumptions stated above.

The linear burning rate for each propellant can now be determined from either Equation (30) or Equation (32) in combination with Equation (32a). If the interpolation indicated by use of Equation (30) is selected, the generalized interpolation sub-routine* is employed. The mass-fractions burned, z_i 's, during a small time interval, dt , are determined by integration of Equation (29). The surface areas of the unburned propellant (see Appendix A) are used in this initial calculation. The Runge-Kutta method of numerical integration, as modified by Gill,⁽¹²⁾ is commonly used for the solution of sets of ordinary differential equations and has been employed here.

Calculation of the temperature, T , from Equation (19) and the volume available for propellant gas, V_c , from Equation (22), will allow the calculation of the new space-mean pressure, \bar{p} , at time, dt , from Equation (26). The surface areas of the now partially burned propellants are computed from equations presented in Appendix A. All results of interest are printed-out at this time ** and these results used as initial conditions for calculations during

* See Reference (18) for interpolation by divided differences.

** See Appendix C for listing of output data.

the ensuing time-interval. Those terms in Equations (17), (19), and (22) which involve velocity or displacement are zero during this phase of the computation. This calculation-loop is continued until the space-mean pressure exceeds a pre-selected "shot-start" pressure and the projectile starts to move. Phase I, which has been arbitrarily defined, ends at this time.

Phase II requires the addition of the equations of motion to the sequence followed during Phase I. Equations (27), (39), (40), and (41) are used to calculate the values of the acceleration, velocity, and displacement of the projectile at the end of each time interval. Integration specified in Equations (40) and (41) is again performed by the Runge-Kutta-Gill method. Values of velocity and displacement are now available for use in terms of Equations (17), (19), and (22). To compute values for $E_{p_r} = A \int_0^x p_r dx$, which is one of the terms in Equation (19), the generalized interpolation sub-routine must be used to obtain p_r from the tabular information described by Equation (34a). This integration is performed by use of the Trapezoidal Rule.*

As time is increased by the addition of small time-intervals, calculations during Phase II are continued around this expanded loop with print-out of appropriate results at the end of each time interval. One at a time, the propellants are completely consumed and this phase is ended. A series of switches has been incorporated in the program to circumvent the necessity of introducing propellants in any special order. In fact, it may not always be possible to predict the exact order in which several different propellants will be burned out. The combination of the propellant switches and the start-of-motion switch makes it possible to handle problems where one or more propellants burn out before the projectile starts to move.

With all propellants consumed, Phase III begins. The mass-fractions burned have all become unity and the equations concerned with burning (Equations (29), (31), and (30) or (32)) are eliminated from the loop. As in the other phases,

* Although the Trapezoidal Rule is a relatively crude method for numerical integration, the accuracy of the p_r versus x data available does not warrant a more accurate and hence more complex method.

results are printed-out at the end of each time-interval. A continual check is made of the displacement of the projectile to determine whether or not it has reached the muzzle of the gun. When the projectile passes the muzzle, Phase III has ended and the program is stopped.

It is possible for the projectile to reach the muzzle (and the program stopped) before Phase II is completed. This would simulate a gun-firing in which unburned propellant is ejected from the muzzle. It is also possible for the program to simulate a firing in which the projectile becomes lodged in the tube. In this case, Phase III is not completed and the program is stopped when the projectile displacement does not increase.

At each time-interval after the beginning of Phase II, the breech pressure is determined from Equation (28) and printed out. This result is not used in the computational routine but is used to compare theoretical and experimental results. A continual check is made of the calculated pressures and the maximum breech pressure is stored with its associated time and projectile displacement. This information is printed-out at the end of the program. Calculations during the last time-interval result in a projectile displacement somewhat greater than the desired distance to the muzzle. A linear interpolation between results at the last two time-intervals is used to obtain results exactly at the muzzle. These results are also printed-out at the end of the program.

Options to Routine

A considerable number of options have been designed and coded for special problems. These include changes which enable the program to be used for guns, or gun-like weapons, which are not of conventional design (Figure 1) and changes which vary the treatment of some of the individual parameters. It is expected that the number of such options will increase as the program is used for a greater number and variety of problems.

Typical options for non-conventional guns are those for gun-boosted rockets, traveling-charge guns, and light-gas guns of the adiabatic compressor type. Examples of options for varied treatment of individual parameters are those for adjusted burning rates (previously mentioned), inhibited propellant surfaces, delayed propellant ignition, variable time-intervals, constant resistive pressure, and resistive pressure as a function of base pressure.

DISCUSSION

No attempt has been made here to present a new and different interior ballistic theory. The objective was to devise a convenient, flexible scheme for performing the tedious numerical calculations required to obtain detailed interior ballistic trajectories. The selection of a program for high-speed digital computers has made it possible to eliminate most of the simplifications of theory required to facilitate mathematical solutions by other methods.

The theory presented as the basis for the computer routine is well-known and has only been modified to account for composite charges. There are several problems present in all interior ballistic calculations and these also prove troublesome here. For example, useful propellant burning rates are not generally available. It is known that burning rates obtained from experimental firings in closed chambers are usually low. The results obtained from limited gun-firings by the authors ⁽¹¹⁾ indicate gun burning rates may be twice closed chamber burning rates under certain conditions. As previously mentioned, optional methods of adjusting closed chamber burning rates have been provided for in this program. One such approach is to consider the burning rate to be a function of the projectile velocity (and possibly a function of the projectile displacement) in addition to its known dependence on pressure. This method results in the use of closed chamber burning rates when the gun chamber is practically a closed chamber (v and x are effectively zero). When the projectile is moving at higher velocities and is further down tube, reasonable increases in burning rates are obtained and used. Other equally important difficulties are associated with the determination of reasonable values for resistive pressure and shot-start pressure.

Considerable versatility has been built into the program. Instead of stopping the computation at the end of Phase III, a new problem can be automatically read into the computer and solved. This multiple-case feature can be employed to advantage for any number of additional problems during a single computer run.

Typical interior ballistic problems were used to compare results obtained from this computer routine with results from other interior ballistic schemes. (13), (14), and (15). The agreement was generally very good when the other

DISCUSSION

No attempt has been made here to present a new and different interior ballistic theory. The objective was to devise a convenient, flexible scheme for performing the tedious numerical calculations required to obtain detailed interior ballistic trajectories. The selection of a program for high-speed digital computers has made it possible to eliminate most of the simplifications of theory required to facilitate mathematical solutions by other methods.

The theory presented as the basis for the computer routine is well-known and has only been modified to account for composite charges. There are several problems present in all interior ballistic calculations and these also prove troublesome here. For example, useful propellant burning rates are not generally available. It is known that burning rates obtained from experimental firings in closed chambers are usually low. The results obtained from limited gun-firings by the authors ⁽¹¹⁾ indicate gun burning rates may be twice closed chamber burning rates under certain conditions. As previously mentioned, optional methods of adjusting closed chamber burning rates have been provided for in this program. One such approach is to consider the burning rate to be a function of the projectile velocity (and possibly a function of the projectile displacement) in addition to its known dependence on pressure. This method results in the use of closed chamber burning rates when the gun chamber is practically a closed chamber (v and x are effectively zero). When the projectile is moving at higher velocities and is further down tube, reasonable increases in burning rates are obtained and used. Other equally important difficulties are associated with the determination of reasonable values for resistive pressure and shot-start pressure.

Considerable versatility has been built into the program. Instead of stopping the computation at the end of Phase III, a new problem can be automatically read into the computer and solved. This multiple-case feature can be employed to advantage for any number of additional problems during a single computer run.

Typical interior ballistic problems were used to compare results obtained from this computer routine with results from other interior ballistic schemes. (13), (14), and (15). The agreement was generally very good when the other

schemes were fairly sophisticated. In addition, detailed interior ballistic trajectories are produced in considerably less time than it takes to calculate maximum pressure and muzzle velocity by other systems. A typical computer solution for a conventional gun takes only 10 seconds if magnetic tape output is used with the BRIESC.

Results from computer simulations have also been compared to experimental data obtained from well-instrumented gun firings. To demonstrate the adequacy of the computer routine, data from a typical 105mm Howitzer firing were processed by the method described in Reference (11). In Appendix D these experimental results are compared with the predicted results obtained from a simulation of this firing.

FORM FUNCTION EQUATIONS

Geometrical Equations

1. Initial Volume of a Propellant Grain

$$V_{g_1} = \frac{\pi}{4} (D_1^2 - N_1 d_1^2) L \quad (A-1)$$

where: V_{g_1} = volume of an unburned propellant grain, in.³

D_1 = outside diameter of grain, in.

N_1 = number of perforations, dimensionless

d_1 = diameter of perforation, in.

L_1 = length of grain, in.

2. Volume of a Partially Burned Propellant Grain

$$V_{g_1} (1 - z_1) = \frac{\pi}{4} \left[(D_1 - u_1)^2 - N_1 (d_1 + u_1)^2 \right] (L_1 - u_1) \quad (A-2)$$

where: z_1 = mass-fraction of 1 th propellant burned at a given time, dimensionless

u_1 = two times the distance each surface has receded at a given time, in.

3. Initial Surface Area of a Propellant Grain

$$S_{g_1} = \pi \left[(D_1 + N_1 d_1) (L_1) + \frac{D_1^2 - N_1 d_1^2}{2} \right] \quad (A-3)$$

where: S_{g_1} = surface area of an unburned propellant grain, in.²

4. Surface Area of a Partially Burned Propellant Grain

$$S_1 = \pi \left\{ \left[(D_1 - u_1) + N_1 (d_1 + u_1) \right] \left[L_1 - u_1 \right] + \frac{(D_1 - u_1)^2}{2} - \frac{N_1 (d_1 + u_1)^2}{2} \right\} \quad (A-4)$$

where: S_1 = surface area of partially burned 1 th propellant grain at a given time, in.².

Equations for Newton-Raphson Method* for Finding Approximate Values of the Real Roots of a Numerical Equation

1. Rearrange Equation (A-2) to set $f(u_1) = 0$:

$$\begin{aligned} f(u_1) = & \frac{\pi}{4} \left\{ (N_1 - 1) u_1^3 - \left[L_1(N_1 - 1) - 2(D_1 + N_1 d_1) \right] u_1^2 \right. \\ & - \left[2L_1(D_1 + N_1 d_1) + (D_1^2 - N_1 d_1^2) \right] u_1 \\ & \left. + L_1 (D_1^2 - N_1 d_1^2) \right\} - V_{g_1} (1 - z_1) \end{aligned} \quad (A-5)$$

2. Differentiate Equation (A-5) with respect to u_1 :

$$\begin{aligned} f'(u_1) = & \frac{d [f(u_1)]}{du_1} = \frac{\pi}{4} \left\{ 3(N_1 - 1) u_1^2 \right. \\ & - 2 \left[L_1(N_1 - 1) - 2(D_1 + N_1 d_1) \right] u_1 \\ & \left. - \left[2L_1(D_1 + N_1 d_1) + (D_1^2 - N_1 d_1^2) \right] \right\} \end{aligned} \quad (A-6)$$

3. The value of the root of Equation (A-2) is then:

$$u_{1+1} = u_1 - \frac{f(u_1)}{f'(u_1)} \quad (A-7)$$

where: u_{1+1} = the improved value of the root, where the first estimate of the root is u_1 .

Procedure

1. For each propellant, determine z_1 by integration of Equation (29). In the initial calculation of each z_1 , Equation (A-3) is used to compute each S_1 ($S_1 = S_{g_1}$ when $u_1 = 0$). For subsequent calculations of each z_1 , Equation (A-4) is used with u_1 determined as described below.

* See Reference (16) for a discussion of this method.

2. The z_i 's obtained from Equation (29) are used to compute the u_i 's from Equation (A-7) and then the new S_i 's are computed from Equation (A-4).

In the initial calculation of u_i , the first estimate of its value is zero.

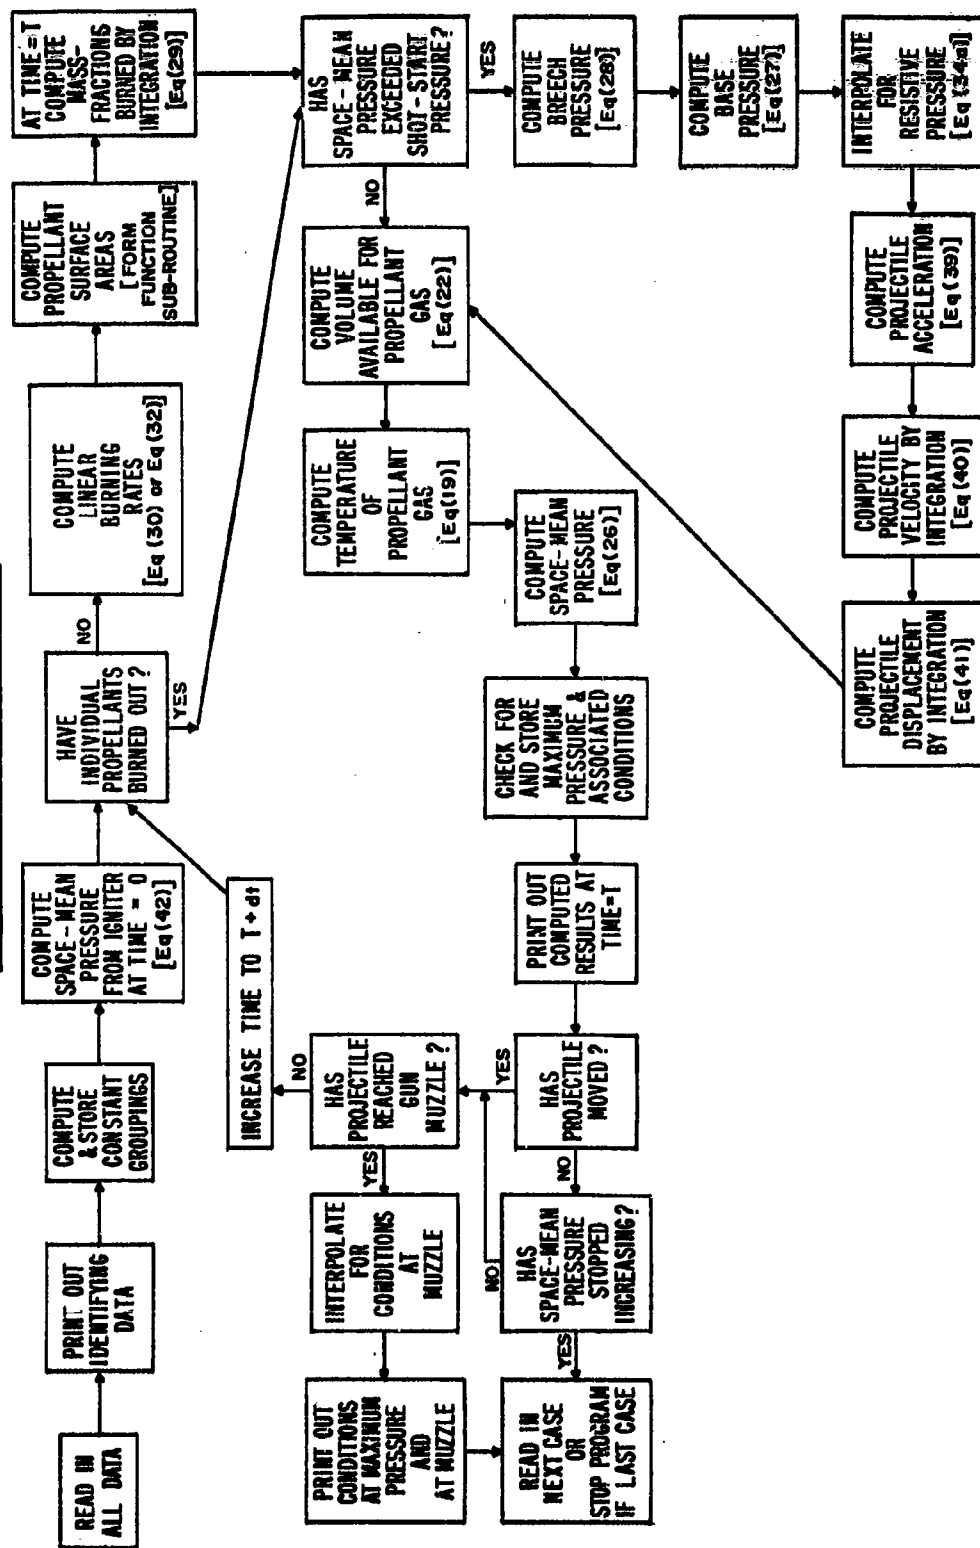

Equation (A-7) is used to calculate the improved value, u_{i+1} . With u_{i+1} as the estimate, Equation (A-7) is used again to calculate a further-improved value, u_{i+2} . This procedure is continued until the improvement is less than 10^{-5} inch.

APPENDIX C

Input and Output Data

1. Input Data
2. Output Data
3. Sample of Output Format

1. INPUT DATA

	<u>Units</u>	<u>Program Symbol</u>
<u>Gun Constants</u>		
Weight of Projectile	lb	WP
Length of Gun Tube	in.	XM
Empty Volume of Chamber	in. ³	VO
Cross-sectional Area of Bore	in. ²	AP
Shot-Start Pressure	psi	PE
Pidduck-Kent Constant	dimensionless	DEL
Resistive Pressures	psi	PRL,J
Travel of Projectile Corresponding to each of 20 Resistive Pressures	in.	XCL,J
Diameter of Bore	in.	D
<u>Propellant Physical Constants</u>		
Weights of Propellants	lb	CL,J
Weight of Igniter	lb	CI
Densities of Propellants	lb/in. ³	RHOL,J
Outside Diameter of Propellant Grains	in.	DL,J
Diameter of Propellant Perforations	in.	DFL,J
Length of Propellant Grains	in.	LL,J
Number of Perforations per Grain	dimensionless	NPL,J
Number of Propellants	dimensionless	NL
<u>Propellant Thermodynamic Constants*</u>		
Forces of Propellants	in.-lb/lb	FL,J
Force of Igniter	in.-lb/lb	FI

* See Reference (17) for these data.

	<u>Units</u>	<u>Program Symbol</u>
Ratios of Specific Heats of Propellants	dimensionless	GAL,J
Ratio of Specific Heats of Igniter	dimensionless	GAI
Covolumes of Propellants	in. ³ /lb	COVL,J
Adiabatic Flame Temperatures of Propellants	°K	TOL,J
Adiabatic Flame Temperature of Igniter	°K	TOI
Burning Rate Coefficients	$\frac{\text{in.}}{\text{sec}} - \frac{1}{\text{psi}^\alpha}$	BET1,J
Burning Rate Exponents (α 's)	dimensionless	ALP1,J
Burning Rate Velocity Coefficient	$\frac{\text{in.}}{\text{sec in./sec}}$	KV
Burning Rate Displacement Coefficient	$\frac{\text{in.}}{\text{sec-in.}}$	KX
<u>Miscellaneous Constants</u>		
Time Interval	sec	DT
Estimated Muzzle Velocity	ft /sec	EVP
Maximum Allowable Breech Pressure	psi	PPMAX

2. OUTPUT DATA

Identifying Data

The complete list of input data is printed out to permanently identify the computation.

	<u>Units</u>	<u>Program Symbol</u>
<u>Trajectory Data</u>		
Time	millisec	TM
Travel of Projectile	in.	XI
Travel of Projectile	ft	XF
Breech Pressure	psi	PBR
Space-mean Pressure	psi	PT
Base Pressure	psi	PB
Velocity of Projectile	ft/sec	V
Acceleration of Projectile	ft/sec ²	AF
Temperature of Propellant Gas	^o K	TEMP
Volume behind Projectile available for Propellant Gas	in. ³	VC
Resistive Pressure	psi	PR
Total Surface Area of Propellants	in. ²	ST
Mass-fractions of Propellants Burned	dimensionless	Y3,J
Mass Burning Rates of Propellants	lb/sec	DCZ1,J
Linear Burning Rates of Propellants	in./sec	R1,J
Surface Areas of Propellants	in. ²	S1,J

<u>Summary Data</u>	<u>Units</u>	<u>Program Symbol</u>
Muzzle Velocity	ft/sec	VMAX
Maximum Breech Pressure	psi	PMAX
Travel at Maximum Breech Pressure	in.	XPMAX
Time at Maximum Breech Pressure	sec	TPMAX
Muzzle Pressure (Base of Projectile)	psi	PBMAX

<p>AD Accession No. _____</p> <p>Ballistic Research Laboratories, AFG THE SIMULATION OF INTERIOR BALLISTIC PERFORMANCE OF GUNS BY DIGITAL COMPUTER PROGRAM Paul G. Baer and Jerome M. Frankie REL Report No. 1185 December 1962</p> <p>ROT & E Project No. 1M010501A004 UNCLASSIFIED Report</p>	<p>UNCLASSIFIED</p> <p>Interior ballistics - Mathematical Analysis Guns - Interior ballistics</p>
<p>When non-conventional guns are to be considered or when detailed design information is required, interior ballistic calculations become more difficult and time-consuming. To deal with these problems, the equations which describe the interior ballistic performance of guns and gun-like weapons have been programmed for the high-speed digital computers available at the Ballistic Research Laboratories. The major innovation contained in the equations derived in this report is the provision for use of propellant charges made up of several propellants of different chemical compositions and different granulations. Results obtained by the method described in this report compare favorably with those of other interior ballistic systems. In addition, considerably more detail is obtained in far less time. A comparison with experimental data from well-instrumented gun-firings is also presented to demonstrate the validity of this method of computation.</p>	<p>When non-conventional guns are to be considered or when detailed design information is required, interior ballistic calculations become more difficult and time-consuming.
